**Abstract.** This work was aimed to design efficient catalysts for  $N<sub>2</sub>O$  decomposition at low temperatures. Cobalt oxide  $(C_{03}O_4)$  was prepared by hydrothermal, precipitation and combustion methods and tested for  $N<sub>2</sub>$ O decomposition. It was found that the catalysts prepared by solution combustion synthesis were most active for this reaction. Subsequently, a series of ceria (CeO<sub>2</sub>) supported Co<sub>3</sub>O<sub>4</sub> catalysts (xCeCo) were prepared by solution combustion method and used them for  $N_2O$  decomposition. All the catalysts were characterized by analytical methods like XRD, TEM, BET, XPS, UV-Vis, Raman and  $H_2$ -TPR. It was found that 10 and 20 wt..% loading of CeO<sub>2</sub> on Co<sub>3</sub>O<sub>4</sub> promoted the activity of Co<sub>3</sub>O<sub>4</sub> towards N<sub>2</sub>O decomposition, whereas, higher loading of  $CeO<sub>2</sub>$  reduced the activity. Typical results indicated that addition of  $CeO<sub>2</sub>$  increases the surface area of  $Co<sub>3</sub>O<sub>4</sub>$ , and improves the reduction of  $Co<sup>3+</sup>$  to  $Co<sup>2+</sup>$  by facilitating the desorption of adsorbed oxygen species, which is the rate-determining step for the  $N_2O$  decomposition over  $Co<sub>3</sub>O<sub>4</sub>$  spinel catalysts. Optimal  $CeO<sub>2</sub>$  loading can increase both dispersion and surface area of  $Co<sub>3</sub>O<sub>4</sub>$  catalysts and weaken the Co–O bond strength to promote  $N_2O$  decomposition.

**Keywords.** Low temperature  $N_2O$  decomposition; cobalt oxide; ceria; solution combustion synthesis; citric acid.

## **1. Introduction**

It has been reported that nitrous oxide  $(N_2O)$  is one of the ozone-depleting substances.<sup>1</sup> Also, with a global warming potential of nearly 300 times more than  $CO<sub>2</sub>$ ,  $N_2O$  is a potent greenhouse gas.<sup>2</sup> About 40% of global N<sub>2</sub>O emissions are a result of human activities. Major sources are agriculture, transportation, combustion of fossil fuels and industries involved in preparation of adipic aid, nitric acid, *etc*. Apart from these, many natural processes like nitrogen cycle and breakdown of nitrogen by bacteria in soil and oceans are also responsible for  $N_2O$  emissions. Also,  $N_2O$  is released as a by-product during the abatement of other environmentally harmful species like three-way catalytic decomposition of  $NO_x$ , hydrocarbons, *etc*.<sup>3</sup> Hence the growing level of  $N<sub>2</sub>O$  in atmosphere is a major concern. To curb this, many new ways of emission reduction are being investigated. Broadly there can be two possible ways; either controlling the amount of  $N_2O$  being released or decomposition of the released  $N_2O$ . Latter option turns out to be more realistic as a lot of time is needed to bring down the current emission levels. Catalytic decomposition of  $N_2O$  is an extensively studied area.<sup>3</sup> Starting from the usage of metals like Ir, Cu dispersed on suitable supports,  $4,5$  to metals supported with alkali dopants,  $6.7$  improvisations have been made by using pure, supported<sup>8</sup> and mixed metal oxides. $9-12$ Among the various transition metal oxides, cobalt oxide  $(Co_3O_4)$  has shown promising activity for decomposition of  $N_2O$ .  $Co_3O_4$  spinel has a cubic structure and is expected to have 1:2 ratio of  $Co^{+3}$ :  $Co^{+2}$  ions. However, the presence of non-stoichiometry results in an increased concentration of oxide ions, which in turn causes an increased ratio of  $\text{Co}^{+3}$  due to charge transfer to oxygen. Octahedral site is assumed to be the catalytically active site of pure cobalt oxide. However, an enhanced activity is seen if  $Co^{+3}$  is present instead of  $Co^{+2}$  in octahedral site.<sup>13</sup> The redox couple of  $Co^{+3}/Co^{+2}$  plays an important role in the usage of  $Co<sub>3</sub>O<sub>4</sub>$  as catalyst in numerous other reactions like oxidation of Carbon monoxide  $(CO)^{14}$  and ammonia  $(NH_3)$ <sup>15</sup> Pristine Co<sub>3</sub>O<sub>4</sub> has numerous limitations for its use as catalyst for  $N_2O$  decomposition, especially at higher temperatures because of reduction of its active phase to CoO. Further, the catalyst particles tend to sinter and form clusters which results in reduced activity. Hence, a dopant is needed which apart from stabilizing the catalyst, may also provide additional and enhanced

<sup>∗</sup>For correspondence

S K Mahammadunnisa and T Akanksha have equal contribution

catalytic activity. Among the various structural modifiers available, ceria  $(CeO<sub>2</sub>)$  seems to be a good candidate because of its well-known 'oxygen storage capacity'.  $CeO<sub>2</sub>$  plays an important role in two most important industrial processes: three-way catalysis (TWC) and fluid catalytic cracking (FCC). Apart from this,  $CeO<sub>2</sub>$  has been used in the treatment of gaseous emissions like SOx, and liquid wastes. However, in all these processes it always acts as structural/electronic promoter and/or as co-catalyst.<sup>16</sup> Hence, effective stabilization of the dispersed state of transition metal oxides by preventing sintering, retention of their high surface area and its redox/oxidation properties along with high oxygen mobility further encourage the usage of CeO<sub>2</sub> in combination with  $CoOx$ .<sup>17</sup> Earlier Xue *et al.*, had reported decomposition of  $N_2O$  over cerium oxide promoted cobalt oxide catalyst prepared by coprecipitation method.<sup>18</sup> However, it is well-known that catalyst activity can be modified by the preparatory methods.<sup>19</sup> With this background, we first prepared pure  $Co<sub>3</sub>O<sub>4</sub>$  by using solution combustion, co-precipitation and hydrothermal synthesis and tested their activity for  $N_2O$  decomposition. Subsequently, the best one was chosen and was supported with varying amounts of  $CeO<sub>2</sub>$  so as to get a series of  $CeO<sub>2</sub>$  doped  $Co<sub>3</sub>O<sub>4</sub>$ (xCeCo) catalysts and studied their activity for  $N_2O$ decomposition.

## **2. Experimental**

## 2.1 *Catalyst preparation*

 $Co<sub>3</sub>O<sub>4</sub>$  was prepared by three different preparation methods, namely solution combustion, co-precipitation and hydrothermal synthesis.

2.1.1 *Hydrothermal synthesis of*  $Co<sub>3</sub>O<sub>4</sub>$ *:* Cobalt nitrate, cetyltrimethyl ammonium bromide (CTAB) and urea were dissolved in calculated amount of water and stirred for 10 min. They were then transferred to a Teflon beaker and kept in an autoclave maintained at 160◦C for 15 h. After the completion of reaction, contents were filtered and washed with water. They were then calcined at 500◦C for 12 h so as to get the desired catalyst.

2.1.2 *Co-precipitation synthesis of*  $Co<sub>3</sub>O<sub>4</sub>$ *:* Cobalt nitrate was dissolved in optimum amount of water and was kept for stirring. To this, 2 M sodium hydroxide solution was added drop wise to maintain pH around 11. The precipitate so obtained was left undisturbed for ageing overnight. Later, it was filtered and washed with hot water. Solid so obtained was then calcined at 450◦C for 12 h to get the desired catalyst.

2.1.3 *Solution combustion synthesis of*  $Co<sub>3</sub>O<sub>4</sub>$ *:* Cobalt nitrate hexahydrate,  $Co(NO<sub>3</sub>)<sub>2</sub>$ .6H<sub>2</sub>O (taken as cobalt precursor) and citric acid  $(C_6H_8O_7)$  (taken as fuel, purchased from Sigma) were dissolved in minimum amount of water and the solution was sonicated for 15 min. Fuel: oxidant ratio  $(\Phi)$  was fixed at 1:1. The resultant solution was kept on hot plate so as to get froth. This was then placed inside a preheated furnace maintained at 450◦C for 15 min. The spongy solid so obtained was crushed into a fine powder and stored for further characterization and reactions.

2.1.4 *Solution combustion synthesis of CeO*<sub>2</sub> *doped*  $Co_3O_4$  (xCeCo) catalysts: A series of CeO<sub>2</sub> loaded  $Co<sub>3</sub>O<sub>4</sub>$  catalysts was prepared by solution combustion method. Amount of  $CeO<sub>2</sub>$  was varied from 0 to 100%  ${100 * xCeO<sub>2</sub>}/((1-x) Co<sub>3</sub>O<sub>4</sub> + xCeO<sub>2</sub>)}$  so as to get xCeCo catalysts where x denotes the mole fraction of CeO2. Calculated amounts cobalt nitrate, ceric ammonium nitrate  $((NH_4)_2Ce(NO_3)_6.6H_2O)$  and citric acid were dissolved in minimum amount of water. Contents were sonicated for 15 min and later concentrated on a hot plate so as to get froth. Then they were taken inside a preheated furnace maintained at 450◦C for 15 min. Solid so obtained was crushed to a fine powder so as to get desired xCeCo catalysts.

## 2.2 *Catalyst Characterization*

Synthesised catalysts were characterized by various methods such as XRD, Raman, BET and temperature programmed reduction (TPR). The as-synthesized samples were characterised by X-ray diffractometry using a computerized PAN analytical X'pert pro X-ray diffractometer using Cu  $K\alpha = 1.541$  Å radiation, 30 mA and 40 kV. The step scans were taken over a 2θ range of 0 to 90 $^{\circ}$ . The N<sub>2</sub> adsorption-desorption isotherms were obtained by using NOVA 2200e equipment. Specific surface area was measured from these isotherms by applying the Brunauer-Emmett-Teller (BET) method. Raman spectra of the samples were obtained using Bruker senterra dispersive Raman microscope. Diffuse UV-Vis reflectance spectra of the  $Co<sub>3</sub>O<sub>4</sub>$  catalysts prepared by different methods and xCeCo catalysts were collected using Shimadzu UV-Vis spectrophotometer (UV-3600) with a spectral grade  $BaSO<sub>4</sub>$  as reference. X-ray Photoelectron Spectroscopy (XPS) data of the combustion synthesized catalysts were recorded by

an Axis Ultra instrument under ultra-high vacuum conditions (10<sup>−</sup><sup>8</sup> Torr) and using a monochromatic Al Ka X-ray source (1486.6 eV). The Transmission Electron Microscopy (TEM) image was recorded using FEI model TECNAI G 220 S-Twin equipment. Temperature Programmed Reductions (TPR) experiments were carried out in a flow system (Quantachrome autosorb-IQ automated gas sorption Analyzer) equipped with a thermal conductivity detector (TPR-TCD). For TPR measurements, 50 mg of the sample was sandwiched between quartz wool plugs in a U-shaped quartz reactor and flushed with He for 30 min. The TPR profiles were obtained by heating the sample from room temperature to the desired temperature (600 $°C$ ) in 10%  $H_2$  in Ar, (gas flow rates 40 mL/min and heating rate of 10◦C/min) and the gaseous products were sampled through a fine control leak valve to TCD after passing through a cold trap to remove  $H_2O$ . Quantitative analysis was done by integrating the reduction signal and comparison was made by pre-calibrated signals.

#### 2.3 *Activity measurements*

In order to test for activity, 0.5 g of catalyst was placed in a quartz reactor which was then placed in a furnace maintained at 25◦C. The inlet of the reactor was connected to  $N_2O$  (10%  $N_2O$  in Ar) gas maintaining a flow rate of 60 mL/min by using mass flow controllers (GFC-17, Aalborg-USA). Products were analysed by means of gas chromatography (Varian 450 GC) equipped with a thermal conductivity detector (TCD). The activation energy was estimated from the Arrhenius plot. $20$  The conversion of  $N_2O$  was calculated as follows eq. (1),

% of 
$$
N_2 O_{conv} = \frac{N_2 O_{in} - N_2 O_{out}}{N_2 O_{in}} \times 100
$$
 (1)

# **3. Results and Discussion**

## 3.1 *Characterization results*

3.1.1 *Powder X-Ray Diffraction (P-XRD) of*  $Co_3O_4$ *catalysts*: Powder XRD patterns of Co<sub>3</sub>O<sub>4</sub> prepared by combustion, co-precipitation and hydrothermal synthesis are shown in Figure 1. The patterns of  $Co<sub>3</sub>O<sub>4</sub>$ show characteristic peaks of (220), (311), (222), (400),  $(511)$  and  $(520)$  planes, corresponding to  $Co<sub>3</sub>O<sub>4</sub>$  spinel structure.

Figure 2 represents the XRD patters of xCeCo catalysts. The XRD patterns show prominent peaks at  $2\theta$  (deg) values of 19.1, 31.4, 36.8, 38.6, 44.9, 56.3, 59.3 and 65.4 which are indexed, respectively, as (111), (220), (311), (222), (400), (422), (511) and (440)

planes of fcc structure of  $Co<sub>3</sub>O<sub>4</sub>$  with space group of  $Fd_{3m}$  (227).<sup>20</sup> The diffraction lines corresponding to the ceria phase started appearing after 40% ceria content i.e., 40CeCo onwards. The intensity of  $Co<sub>3</sub>O<sub>4</sub>$  signals increases with the cobalt content.

<b>Catalyst</b>	Surface area $(m^2g^{-1})$	Lattice parameter $(\check{A})$		<b>XRD</b> Particle diameter (nm)

CeO <sub>2</sub>	80	5.414		18	

**Table 1.** Surface area, lattice parameters and particle diameter of xCeCo catalysts.

**Table 2.** Surface area of Co<sub>3</sub>O<sub>4</sub> catalysts.

Catalyst	Preparatory method	Surface area $(m^2g^{-1})$
Co <sub>3</sub> O <sub>4</sub>	Solution combustion	50
Co <sub>3</sub> O <sub>4</sub>	Co-precipitation	35
Co <sub>3</sub> O <sub>4</sub>	Hydrothermal	つつ

Lattice constants of both  $CeO<sub>2</sub>$  and  $Co<sub>3</sub>O<sub>4</sub>$  were calculated and the resulting values are given in Table 1. The  $CeO<sub>2</sub>$  lattice constant in pristine ceria catalyst is 5.416 Å. The lattice constant of  $Co<sub>3</sub>O<sub>4</sub>$  and  $Co<sub>3</sub>O<sub>4</sub>$  in 90 to 50CeCo is equals 8.18 Å (Table 1).

3.1.2 *Surface area (BET analysis) of Co*3O<sup>4</sup> *catalysts*: Specific surface areas of the three  $Co<sub>3</sub>O<sub>4</sub>$  catalysts are shown in Table 2. As seen in the Table 2, sample prepared by solution combustion synthesis had maximum surface area followed by co-precipitation and hydrothermal synthesis, and the latter had the least specific surface area.

The specific surface area of xCeCo catalysts are given in Table 1. The specific surface area of xCeCo catalyst increased upon  $CeO<sub>2</sub>$  loading. Pure  $Co<sub>3</sub>O<sub>4</sub>$  (solution combustion sample) had specific surface area of 50  $\text{m}^2 \text{g}^{-1}$  but it increased to 78  $\text{m}^2 \text{g}^{-1}$  in 50CeCo catalyst. Pure  $CeO<sub>2</sub>$  had the maximum specific surface area (80)  $\rm m^2 g^{-1}$ ). The above results indicate that CeO<sub>2</sub> loading results in formation of small crystallites thereby giving large surface area.<sup>21</sup>

## 3.1.3 *Raman spectroscopy*

3.1.3a *Co*3O4*catalysts*: Raman spectra of the three  $Co<sub>3</sub>O<sub>4</sub>$  samples are shown in Figure 3.  $Co<sub>3</sub>O<sub>4</sub>$  belongs to the space group Oh,  $\text{Ed}_{3m}$  and bulk  $\text{Co}_3\text{O}_4$  has five major Raman active modes around 194, 482, 522, 618 and 691 cm<sup>-1</sup> assigned to F<sub>2g</sub>, E<sub>g</sub>, F<sub>2g</sub>, F<sub>2g</sub> and A<sub>1g</sub>, respectively. The most intense  $A_{1g}$  peak (691 cm<sup>-1</sup>) is

**Figure 3.** Raman spectra of  $Co<sub>3</sub>O<sub>4</sub>$  catalysts prepared by different methods.

assigned to the octahedral site  $CoO<sub>6</sub>$  symmetry and the  $E_g$  and  $F_{2g}$  peaks are together assigned to the tetrahedral site  $CoO<sub>4</sub>$  symmetry.<sup>22,23</sup> All the samples give the characteristic peaks, however the intensity of these peaks are different.

3.1.3b *xCeCo catalysts:* Raman spectra of xCeCo samples prepared by combustion synthesis are shown in Figure 4. CeO<sub>2</sub> is much more Raman active than  $Co<sub>3</sub>O<sub>4</sub>$ and shows only one characteristic Raman peak at 464  $\text{cm}^{-1}$ .<sup>24</sup> As the content of CeO<sub>2</sub> increases, the 484 cm<sup>-1</sup> peak of  $Co<sub>3</sub>O<sub>4</sub>$  gets masked by  $CeO<sub>2</sub>$  peak. Also the intensity of both  $A_{1g}$  and  $F_{2g}$  modes of Co<sub>3</sub>O<sub>4</sub> decreases with the increase in  $CeO<sub>2</sub>$  content. There occurs a considerable broadening of peaks too. It might be due to change in the composition of  $Co<sub>3</sub>O<sub>4</sub>$  oxide; change in  $Co^{+2}$ :  $Co^{+3}$  ratio. When a perfectly octahedral metal oxide undergoes displacement by other metal ions to generate a mixed metal oxide, its Raman spectrum gets broadened due to interactions between different metals.

**Figure 4.** Raman spectra of xCeCo catalysts.

## 3.1.4 *Diffuse reflectance UV-Vis spectral analyses*

3.1.4a *Co*3O<sup>4</sup> *catalysts*: The UV–Visible spectra of the three  $Co<sub>3</sub>O<sub>4</sub>$  catalysts are shown in Figure 5. There are two bands corresponding to the two transitions

**Figure 5.** Diffuse reflectance UV-Vis spectra of  $Co<sub>3</sub>O<sub>4</sub>$ catalysts prepared by different methods.

occurring in the  $Co<sub>3</sub>O<sub>4</sub>$  spinel. Both the transitions are ligand to metal charge transfer transitions. The lower wavelength band corresponds to  $O^{-2}$  to  $Co^{+2}$  transition while the higher energy band corresponds to  $O^{-2}$  to  $Co^{+3}$  transition.<sup>25</sup>

3.1.4b *xCeCo catalysts*: Figure 6 represents UV-Vis spectra of xCeCo catalysts. The characteristic bands of  $Co<sub>3</sub>O<sub>4</sub>$  are present in these samples too, however the absorbance changes with the introduction of  $CeO<sub>2</sub>$ . The lower wavelength band corresponding to O<sup>-2</sup> to Co<sup>+2</sup> LMCT transitions suffers a red shift while the higher wavelength band corresponding to  $O^{-2}$  to  $Co^{+3}$  remains almost unchanged. This implies that  $CeO<sub>2</sub>$  doping interacts with  $Co^{+2}$  more than  $Co^{+3}$  and stabilizes it more. This decreases the energy separation between  $O^{-2}$  and  $Co^{+2}$  levels which facilitates LMCT transition. This is reflected in the intensities of the two bands. There is an increase in the intensity of first band with an increase in  $CeO<sub>2</sub>$  content.

## 3.1.5 *Temperature programmed reduction (TPR)*

3.1.5a *Co*3O<sup>4</sup> *catalysts*: Hydrogen temperature programmed reduction is a very convenient technique for studying the reduction behaviour of catalysts qualitatively. The reducibility of the catalysts plays an important role for supplying of active oxygen. There exists two kinds of oxygen ions on  $Co<sub>3</sub>O<sub>4</sub>$  surface representing a weaker and stronger local crystal fields sites: one is bonded to one  $Co^{2+}$  and one  $Co^{3+}$  ion, while the other is bonded to three  $Co<sup>3+</sup>$  ions. The easier surface oxygen abstraction at low temperatures has been connected

**Figure 6.** Diffuse reflectance UV-Vis spectra of xCeCo catalysts.

**Figure 7.** TPR profiles of  $Co<sub>3</sub>O<sub>4</sub>$  catalysts prepared by different methods.

to the first kind of oxygen bonding. TPR profiles of the three  $Co<sub>3</sub>O<sub>4</sub>$  catalysts are shown in Figure 7. The lower temperature peak, called the  $\alpha$  peak (as shown in red color), corresponds to the reduction of  $Co^{+3}$  to  $Co^{+2}$  while the one at higher temperature, called  $\beta$  peak (shown in green) is for reduction of  $Co^{+2}$  to metallic cobalt, Co.<sup>26</sup> The finding of peak shift in our TPR studies has demonstrated that the reduction behaviour of the samples was influenced by the preparation method. Lowering the reduction profiles of the bulk  $Co<sub>3</sub>O<sub>4</sub>$  catalyst prepared by combustion method shown in Figure 7 may accompanied by change of shape, crystal structure of  $Co<sub>3</sub>O<sub>4</sub>$  and the formation of a weaker local crystal field sites of  $\text{Co}^{+2}$  ions during combustion compared to the bulk  $Co<sub>3</sub>O<sub>4</sub>$  sample prepared *via* hydrothermal and coprecipitation methods.

3.1.5b *xCeCo catalysts*: Figure 8 shows TPR profiles of xCeCo catalysts. In these cataysts too, the two characteristic reduction peaks of  $Co<sub>3</sub>O<sub>4</sub>$  are present.  $CeO<sub>2</sub>$ exhibits 2 reduction peaks in its TPR profile. The first peak is a low temperature peak which appears at about 500 °C which is assigned for the reduction of surface capped oxygen. While another high temperature peak at about 800◦C corresponds to the reduction of bulk oxygen.<sup>27</sup> Upon introduction of  $CeO<sub>2</sub>$ , the intensity of

Figure 8. TPR profiles of xCeCo catalysts.

the two  $Co<sub>3</sub>O<sub>4</sub>$  peaks changes. An increase in  $CeO<sub>2</sub>$ content increaes the intensity of  $\alpha$  peak and decreases that of  $\beta$  peak. Moreover, a considerable broadening of  $\beta$  peak occurs. The increased intensity implies that more  $Co^{+3}$  species are now undergoing reduction as compared to the  $Co^{+2}$  species. Also, tailing can be explained by weak reducibility of  $CeO<sub>2</sub>$ . Thus, presence of CeO<sub>2</sub> makes reduction of  $\text{Co}^{+2}$  difficult which could be attributed to increased interactions between the two.

3.1.6 *Transmission electron microscopy (TEM)*: Figure 9 shows TEM images taken over the bare  $CeO<sub>2</sub>$  support and 10CeCo catalysts. The areas highlighted by the black circles indicate  $Co<sub>3</sub>O<sub>4</sub>$  particles. Overall,  $Co<sub>3</sub>O<sub>4</sub>$ particles are well-dispersed throughout the entire  $CeO<sub>2</sub>$ particle surfaces examined. The cobalt oxide particles are easily discriminated from the  $CeO<sub>2</sub>$  particles, due to their distinct morphological difference. The  $CeO<sub>2</sub>$  support has a characteristic rectangular shape as seen in the TEM images of pristine CeO<sub>2</sub>, whereas, the Co<sub>3</sub>O<sub>4</sub> particles formed after doping of  $CeO<sub>2</sub>$  are mostly round. Moreover, the  $Co<sub>3</sub>O<sub>4</sub>$  and  $CeO<sub>2</sub>$  phase identifications have also been confirmed through characteristic lattice structure analysis at high resolution with lattice fringe spacing of 0.24 nm for  $Co<sub>3</sub>O<sub>4</sub>$  ([3 1 1]) and 0.27 ([1 0 0]) for  $CeO<sub>2</sub>$ . Lattice parameter values re-establish the fact that the only phases present in the xCeCo catalysts are the individual phases and not mixed oxides.<sup>28</sup>

3.1.7 *X-ray photoelectron spectroscopy (XPS)*: XPS spectra of Co and Ce in 10CeCo are shown in Figure 10. The spectra show Co  $2p_{1/2}$  and  $2p_{3/2}$  peaks at 795 eV and 780 eV, respectively. Some satellite peaks are also

**Figure 9.** TEM images taken over (a)  $CeO<sub>2</sub>$  and (b)  $10CeCo$ ; (c) HRTEM of  $10CeCo$ .

Figure 10. Core level XPS spectra of 10CeCo. (a) Co (2p); (b) Ce(3d).

observed, indicating the presence of both  $+2$  and  $+3$ oxidation states. The XPS spectrum of Ce 3d shows a number of peaks in  $3d_{5/2}$  and  $3d_{3/2}$  region. These peaks are at 882, 889, 898, 900.7, 907.3 and 916 eV.

# 3.2 *Catalytic decomposition of N*2O

3.2.1 N2*O decomposition by Co*3O<sup>4</sup> *catalysts*: Co3O<sup>4</sup> prepared by three different methods was tested for decomposition of  $N_2O$ . The results are shown in Figure 11.  $Co<sub>3</sub>O<sub>4</sub>$  prepared using combustion synthesis showed best activity among the three catalysts. This could be attributed to the fact that combustion synthesis has the ability to introduce more number of defects in the solid which tend to increase the catalytic activity of the material. Also, it results in nanoparticles having large surface area, which is supported by BET analysis and Raman shift values. According to Raman spectra

**Figure 11.** N<sub>2</sub>O decomposition by Co<sub>3</sub>O<sub>4</sub> prepared by different methods.

(Figure 4),  $Co<sub>3</sub>O<sub>4</sub>$  sample prepared *via* hydrothermal synthesis has characteristic peaks at nearly the same position as those found in bulk  $Co<sub>3</sub>O<sub>4</sub>$ ; however, there occurs a deviation of about 13–16 cm<sup>−</sup><sup>1</sup> in case of coprecipitation and combustion samples.

The reason for the deviation is attributed to the optical phonon confinement in nanostructures, which can cause uncertainty in the phonon wave vectors and thus a downshift in the Raman peaks. This is also supported by the smaller particles formed in case of combustion and coprecipitation synthesis while hydrothermal synthesis generates bulk samples.<sup>29</sup> Since the intensity of a particular peak in Raman spectra is an indication of the number of species responsible for that particular peak, it can be inferred from the above spectra that  $Co<sub>3</sub>O<sub>4</sub>$  sample prepared from hydrothermal synthesis has more number of octahedral species  $(Co^{+3})$ as compared to the other two samples. Also, the sample prepared *via* combustion synthesis has more number of tetrahedral species  $(Co^{+2})$ , as observed in UV-Visible spectra (Figure 5). It is clear from the spectra that there occurs a blue shift in both the bands as one moves from coprecipitation to hydrothermal and combustion samples. This shift could be attributed to the quantum confinement of the nanoparticles which again indicates that combustion synthesis produces nanoparticles. Also, from TPR profiles (Figure 7), it is clear that Co<sub>3</sub>O<sub>4</sub> prepared *via* combustion synthesis is an easily reducible species and hence shows better activity than the other two. Hydrothermal sample has these peaks at highest temperature indicating its poor activity. Hence, for furher studies, for preparing  $CeO<sub>2</sub>$  supported/doped  $Co<sub>3</sub>O<sub>4</sub>$  (xCeCo) catalysts, combustion syntehsis was used.

3.2.2 N2*O decomposition by xCeCo catalysts*: Temperature vs % decomposition graphs of xCeCo catalysts are shown in Figure 12. Introduction of  $CeO<sub>2</sub>$  as support to  $Co_3O_4$  improves the activity of the catalyst. However, it is clear from Figure 12 that the promotional effect is strongly dependent on the molar ratio of Ce/Co. In the case of  $Co<sub>3</sub>O<sub>4</sub>$ , the reaction light-off temperature (50% N<sub>2</sub>O conversion) is 300 $\degree$ C, and the complete conversion temperature is 450◦C. Addition of small amounts of  $CeO<sub>2</sub>$  to  $Co<sub>3</sub>O<sub>4</sub>$  increased the activity, so that 10CeCo catalyst showed maximum activity for this reaction. For 10CeCo catalyst, 50% conversion was achieved at 230◦C while 100% conversion was achieved at 350◦C. 20CeCo catalyst too had a greater activity than pure  $Co_3O_4$ . For this catalyst, the reaction reaches 50% conversion at 250◦C and reaches 100% conversion at nearly 380◦C.

With further increase of Ce, the promotion effect of  $CeO<sub>2</sub>$  on the catalytic activity decreased. Pure  $CeO<sub>2</sub>$ was almost inactive for the decomposition of  $N_2O$ below 400◦C (not shown in Figure 12). From BET surface area it is suggested that the increased surface area is an important factor for the high catalytic activity of 10CeCo. In addition, the presence of appropriate amount of  $CeO<sub>2</sub>$  could stabilise the crystallites of  $Co<sub>3</sub>O<sub>4</sub>$ , and thus improve its reduction behaviour. In addition, available active site  $(Co^{2+})$  on the surface of the catalysts decreased because of the surface segregation of  $CeO<sub>2</sub>$ . Therefore, the catalytic activity of  $xCeCo$  $(x > 10 \text{ wt.}\%)$  decreased, even though they have larger surface area than 10CeCo. This is because  $CeO<sub>2</sub>$  causes better dispersion of  $Co<sub>3</sub>O<sub>4</sub>$  particles and thus increases the effective surface area available for the reaction. It is clear from the characterization data that  $CeO<sub>2</sub>$  interacts with  $Co^{+2}$  more than  $Co^{+3}$ . Moreover, the activity

**Figure 13.** Calculation of activation energy for  $Co<sub>3</sub>O<sub>4</sub>$ , 10CeCo and 20CeCo catalysts.

of catalysts decreases as content of  $CeO<sub>2</sub>$  is increased beyond 20 mass%. Hence, it can be proposed that  $\text{Co}^{+2}$ is the active site for the reaction to occur. More  $CeO<sub>2</sub>$ means less availability of  $Co^{+2}$  for the reaction. These interactions are favourable at low  $CeO<sub>2</sub>$  concentrations, because it leads to a better dispersion and stabilization of the active species. On the other hand, at higher concentrations,  $CeO<sub>2</sub>$  might bind more strongly to the active species, thereby rendering them less available for reaction. Activation energies (Ea) of the reaction over xCeCo catalysts are calculated according to the Arrhenius equation and shown in Figure  $13.^{30-33}$

$$

Around 0.5 g of catalyst was taken and kept inside a quartz tube.  $N_2O$  was passed through the inlet at a flow rate of 60 mL min<sup>−</sup><sup>1</sup> . The activation energy varies with the  $CeO<sub>2</sub>$  loading and follows the order:  $Co<sub>3</sub>O<sub>4</sub>$  $(54 \text{ kJ mol}^{-1})$  < 20CeCo (39 kJ mol<sup>-1</sup>) < 10CeCo (36 kJ mol<sup>−</sup><sup>1</sup> ). Especially, the value for the 10CeCo sample is lower than the other active catalysts. Comparison of these results with the TEM analysis suggests that the change of surface morphology and the optimal  $CeO<sub>2</sub>$  loading can increase both dispersion and surface area of the catalyst and reduces the activation energies that can affect the rate of catalytic  $N_2O$  decomposition.

## **4. Conclusions**

In summary, it was shown that preparation methods can affect the activity of the catalyst. Solution combustion method gave the most active  $Co<sub>3</sub>O<sub>4</sub>$  catalyst for N<sub>2</sub>O decomposition and using this we prepared a series of  $CeO<sub>2</sub>$  supported  $Co<sub>3</sub>O<sub>4</sub>$  catalysts to enhance the activity of  $Co<sub>3</sub>O<sub>4</sub>$ . XRD, XPS, FE-SEM and TEM measurements were employed to investigate structural, surface chemical composition as well as the growth process of synthesized nanomaterials and evaluated for  $N_2O$ decomposition. With this method, both the size and shape of  $Co<sub>3</sub>O<sub>4</sub>$  can be controlled under 'one-pot' conditions at relatively low reaction temperatures which can be extended to the preparation of other nanostructures. Lattice oxygen is highly activated because of the Ce introduction and it plays a key role in the decomposition of  $N_2O$  and influences the oxygen storage capacity and other properties such as reducibility and reduction temperature. According to the results, it can be concluded that the optimum amount of ceria is 10wt.% (10CeCo). Among these catalysts, the 10CeCo sample exhibits highest surface area and best catalytic activity for N<sub>2</sub>O decomposition (T<sub>50</sub> = 250<sup>°</sup>C). We propose that an optimal amount of  $CeO<sub>2</sub>$  can increase both dispersion and surface area of catalyst and weaken the  $Co-O$  bond strength to promote the  $N<sub>2</sub>O$  decomposition activity.
